Space Nutrition

One challenge NASA scientists face is providing a balanced, nutritious diet for astronauts. Crews on the International Space Station or even as far away as the Moon can be resupplied with food from Earth in a matter of days. When traveling to another planet, however, a crew must either pack enough food for the entire journey (and the trip home!) or find a way to produce food during the mission. With our current technology, it takes about six months to get to Mars and we will stay there for several months. How much food needs to be packed for such a trip?

1. Calculate how much food you eat on a typical day. Keep a record of everything you eat for one day and use that to calculate your total grams of food per day. (Don’t include water, just food.) Hint: Look at food labels to figure out how many grams are in a serving and what the serving size is. grams per day (g) =

2. At this rate, how much food would a crew of four need for a six-month one-way trip to Mars? hint: Assume the trip begins on January 1st and it is not a leap year.
   
   number of days (d) =
   number of astronauts (a) =
   (g)(d)(a) = kilograms

3. How much food would this crew need for a two-year Mars mission? kilograms

4. According to the book “Space Nutrition,” 50-60% of your calories should come from carbohydrates, 30% from fats and 10-15% from proteins. Look back at the list of foods you ate in one day and calculate the number of grams of each type of food in your diet.

   carbohydrates (c) = g  fats (f) = g  proteins (p) = g
Space Nutrition  (page 2 of 3)

5. Now calculate the total number of calories from each type of food. Proteins and carbohydrates provide 4 calories per gram of food. Fats provide 9 calories/gram.

\[ c = \underline{\quad}\text{calories} \quad f = \underline{\quad}\text{calories} \quad p = \underline{\quad}\text{calories} \]

What were your total \( t \) calories for the day? \( t = \underline{\quad}\text{calories} \)

6. Use the number values above to complete the equations below and calculate the percentage of each type of food calories in your diet. Then color in the pie chart and the key.

\[ 100 \left( \frac{c}{t} \right) = \underline{\quad}\% \text{ carbohydrates} \]
\[ 100 \left( \frac{f}{t} \right) = \underline{\quad}\% \text{ fats} \]
\[ 100 \left( \frac{p}{t} \right) = \underline{\quad}\% \text{ proteins} \]

7. Create a bar graph showing the difference between your diet and the ideal astronaut diet. Assume that the astronaut’s diet is a perfect average of the ranges given in “Space Nutrition.”

Color in the key to match your graph.
8. Based on this data, what changes could you make to improve your diet?

__________________________________________________________________________
__________________________________________________________________________
__________________________________________________________________________
__________________________________________________________________________

9. Now it is your turn to pack the spacecraft! Select a nutritious diet for a two-year Mars mission (see #3 above). Complete the chart below, listing the total number of kilograms for each type of calorie* and giving examples of foods rich in these nutrients.

*To calculate each amount, multiply the total kg by the desired percent and then divide by 100. For example, if the total in #3 were 450 kg, 50% of that would be 450 X 50 ÷ 100 = 225 kg.
